Change password, partly filled

1. The checklist mirrors the server's policy (12–128 characters, upper, lower, digit, symbol) so the user sees what is missing before submitting. The server stays the authority. A new password identical to the current one, or a wrong current password, comes back from the server and appears under the relevant field.

2. Changing your password revokes every refresh token for the user, including this browser's. After success the client signs in again silently with the new password, so the current tab keeps working. The confirmation reads "Password changed. Other devices have been signed out."
